Does mortality explain interannual variability (CV) of EFPs? (Musavi et al. 2017 design, predictor swapped for mortality)

tc>=30, 93 sites (>=3 years raw EFP record) | cv(EFP) = SD(EFP across years) / mean(EFP across years) | weighted lm, weight = 1/sqrt(n_years) (Musavi et al. 2017 Methods)
top row: mean relative disturbance across years | bottom row: max relative disturbance across years | point size = years of data (= the regression weight)

Musavi et al. 2017, Nat. Ecol. Evol. 1:0048 tested cvGPPsat ~ ln(stand age) + species richness (R2=0.55) with this exact weighted−lm design; predictor substituted here for site−level mortality exposure.
