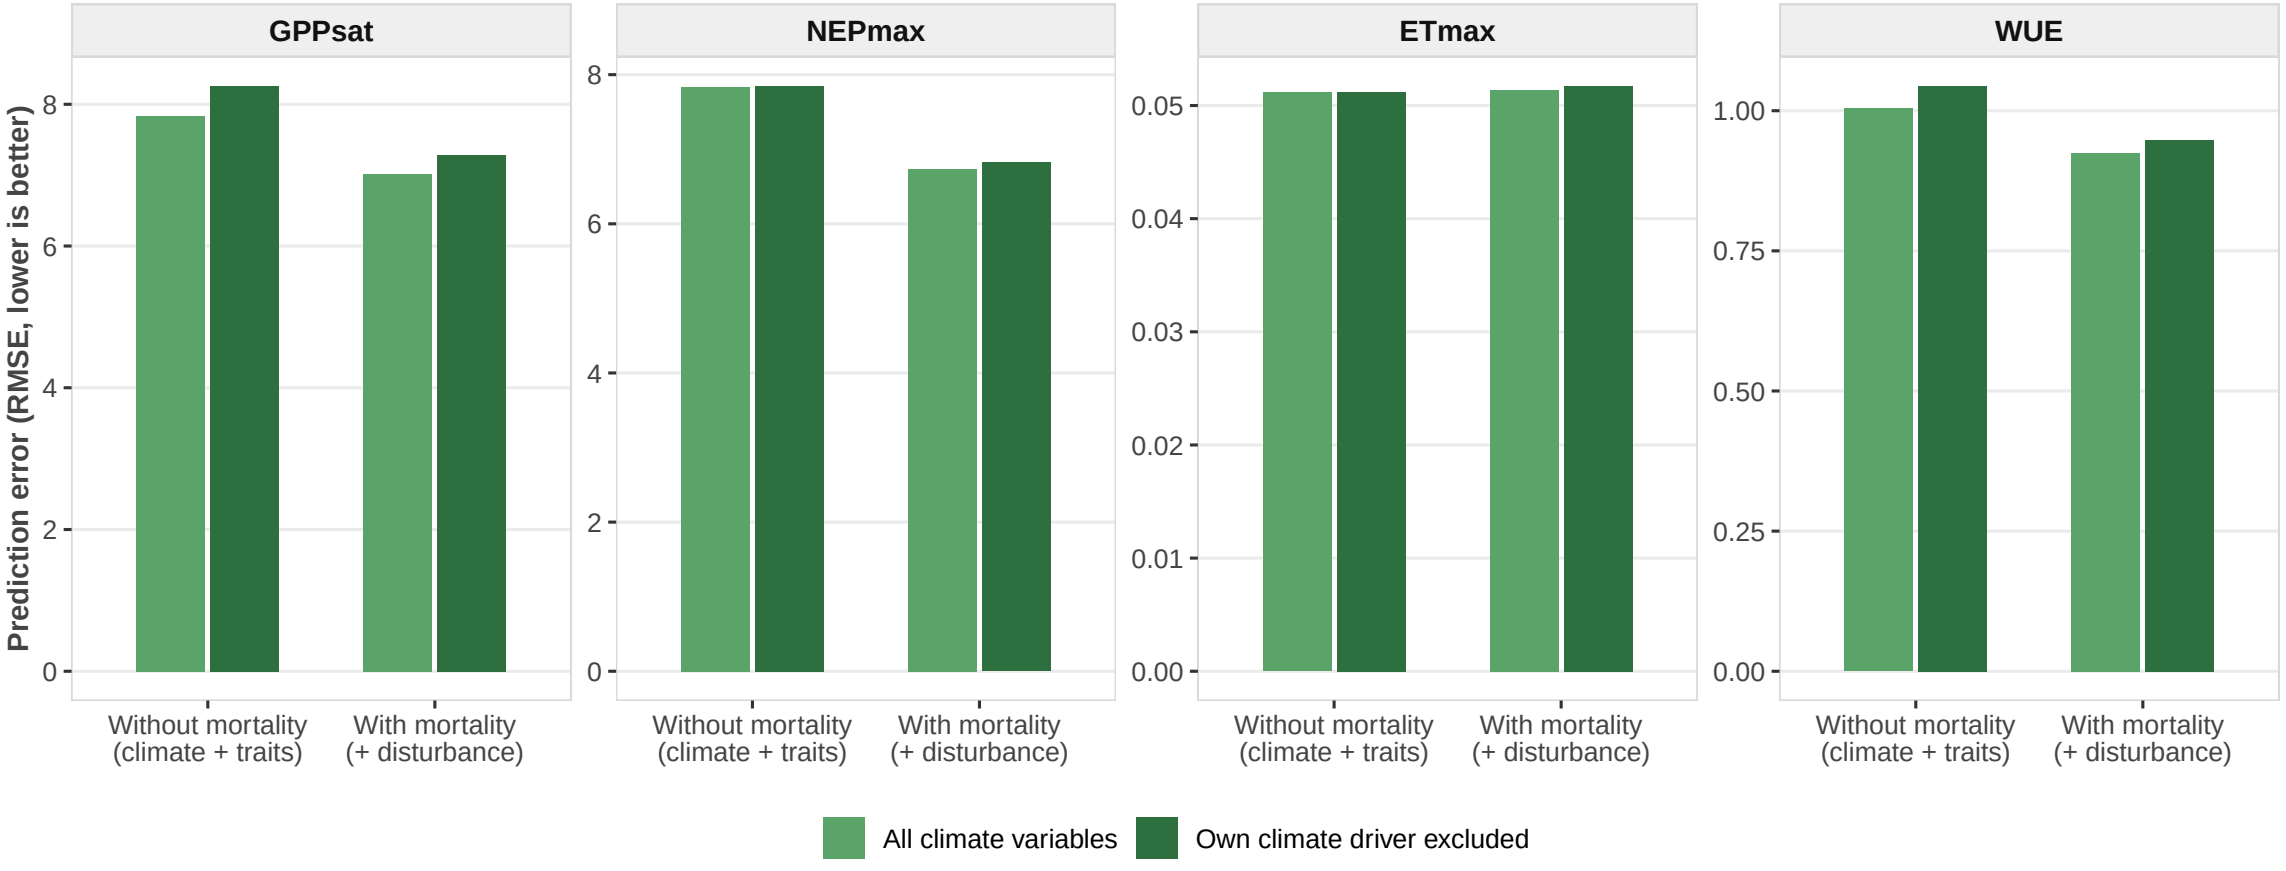
Does mortality improve prediction, even without the climate variables each EFP is derived from?

XGBoost, tc>=30, 93 sites, repeated leave−one−site−out cross−validation (3x80% site subsample)



"Own climate driver excluded": GPPsat without radiation & temperature; NEPmax without radiation; ETmax without temperature; WUE without temperature & VPD − the variables each EFP's own calculation depends on. The benefit of adding mortality holds with or without those variables. Lower bar = better prediction.
