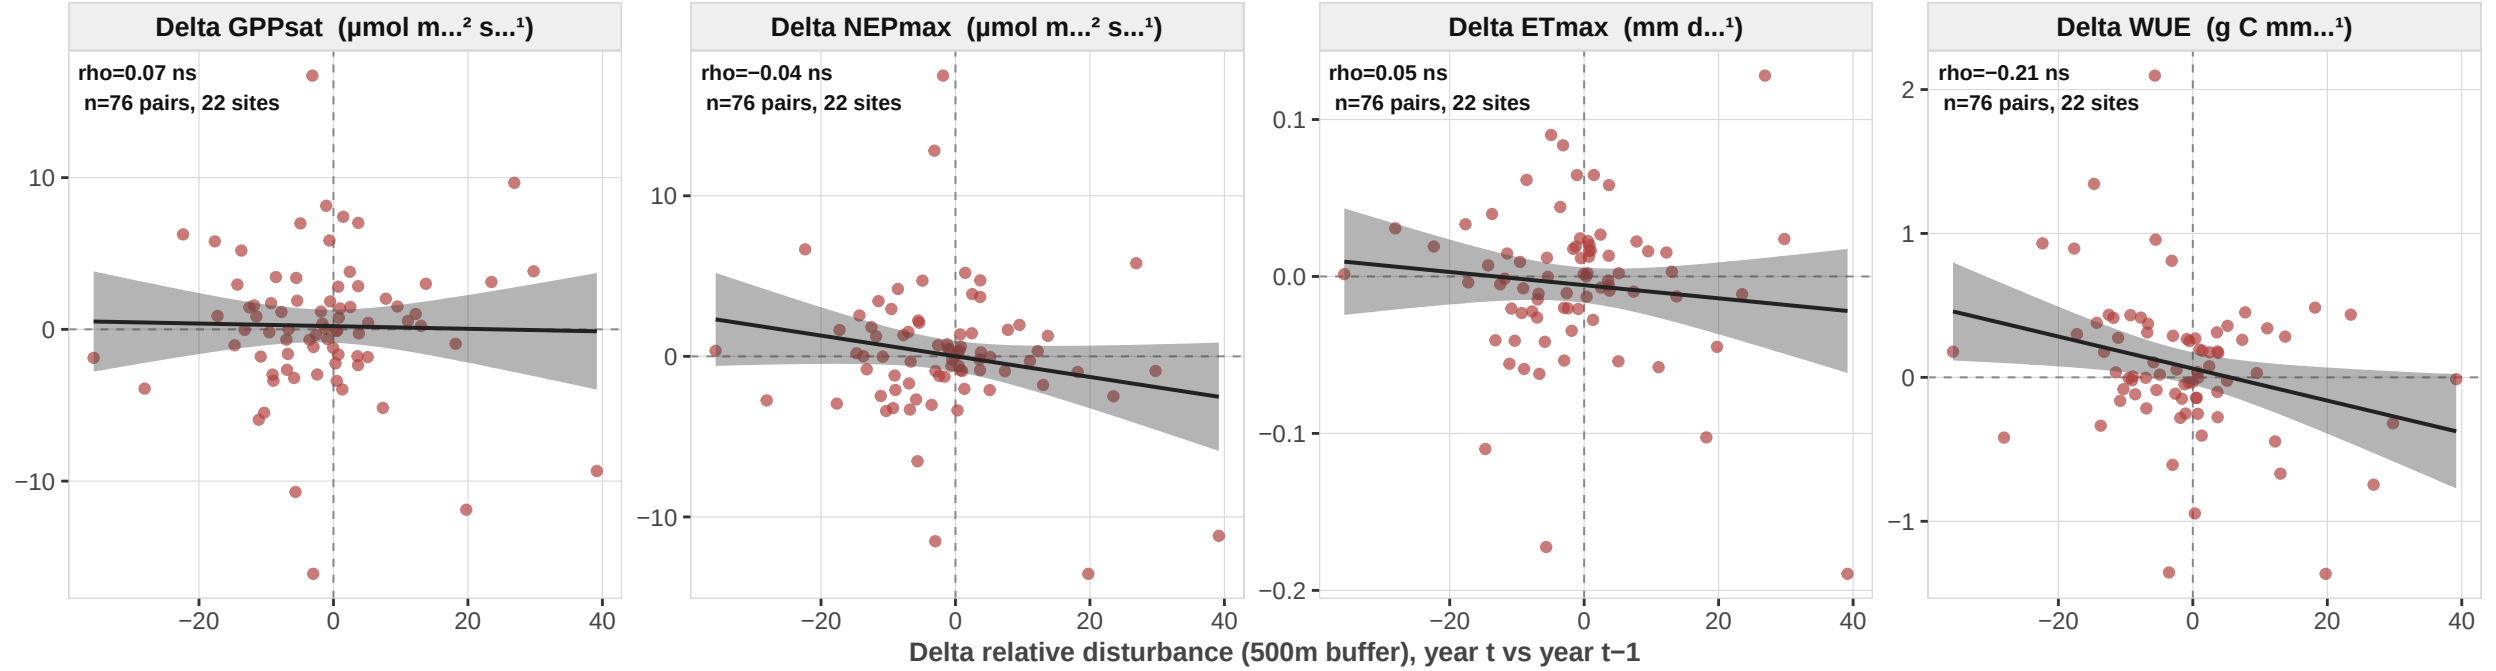
Year−to−year disturbance change vs EFP change − High−disturbance sites only

tc>=30, High−disturbance subset only (23/93 sites, max relative_disturbance_500m > 34.5% NB threshold) | consecutive−year pairs only
linear fit with 95% CI | Spearman rho, BH−FDR across the 4 EFPs



Same design as mortality_change_vs_efp_change.png, restricted to the 23 sites classified High disturbance (same NB threshold as plot_disturbance_vs_clustering.R).
Tests Rene's meeting point #5: does the signal appear once diluting low/no−disturbance sites are excluded?
