Mortality block: SHAP share vs drop-column contribution
deadtrees v5 · 101 sites / 361 site-years · bars = mean of the 12 and 24 month windows, lines = range of the two
A: share of the mortality block's mean |SHAP| (C+T+M) · B: unique information (RMSE up when the family is removed)
C: value on its own (RMSE down when only this family is added to C+T) · B and C retrained with the same tuned settings and folds (XGBoost, LightGBM); AutoGluon only in A
A SHAP share in the mortality block (%)
B Unique: RMSE increase when removed (%)
C Alone: RMSE decrease vs C+T (%)
